eFigure 1. State-Level COVID-19 Deaths Versus State-Level Population by Race/Ethnicity, Crude and Age Standardized

Note. Percentage difference between the share of population of ACS race and ethnicity groups and the share of COVID-19 deaths, aggregated to the nation. If a racial group made up 10% of the population, but experienced 15% of the COVID-19 deaths, the chart would show +.50, or 50% greater share of COVID-19 deaths compared to the share of the population.

eFigure 2. Explanatory Graphic of Queen Contiguity Weights

eFigure 3. Density Plots of Health Factor, SDOH Index, Demographic and Place Variables by CLICs for Each Race and Ethnicity

Note: Distributions in the plots are color coded by race: green represents Black population ($n = 347$, 11.04% of counties); purple represents Hispanic population ($n = 198$, 6.30% of counties); and blue represents white population ($n = 33$, 1.05% of counties). The dashed line represents the distribution of all counties, and the vertical line represents the median in the national distribution.

eTable 1. Social Determinants of Health Indices and Structural Factors

Measure	Description and Data Source
Socioeconomic advantage index (SES)	Include socioeconomic status factors such as poverty, minority status, educational level, and uninsured; this measure is strongly correlated with the Singh et al ¹ areal deprivation index. A low value of this SES index is characterized by a high percentage of population living poverty, with minority status, no high school diploma, and uninsured (low socioeconomic status). (Source: Kolak et al., 2020 ² ; Opioid Environment Policy Scan ³).
Limited mobility index (MOB)	Capture the proportion of older adults and persons with disabilities. A low value of this MOB index is characterized by a high percentage of older adults (aged 65 or over) and people with disabilities. (Source: Kolak et al., 2020 ² ; Opioid Environment Policy Scan ³).
Urban core opportunity index (URB)	Reflects highly urbanized populations experiencing more opportunities and high living costs. A high value of this URB index is characterized by high per capita income, high proportion of renters, high rent burden, and households without a vehicle. (Source: Kolak et al., 2020 ² ; Opioid Environment Policy Scan ³)
Mixed immigrant cohesion and accessibility index (MICA)	Features immigrant populations with traditional family structures and multiple accessibility stressors. A lower value of this MICA index is characterized by a high percentage of families with limited English proficiency, older adults, crowded housing, a lack of health insurance, low high school graduation rates, and fewer single parent households. (Source: Kolak et al., 2020 ² ; Opioid Environment Policy Scan ³)
Population age distribution	We included percent of working age (age 18 to 64) and percent of senior populations (age 65+). (Source: ACS 2019 5-year estimates ⁴)
Rural-urban contexts	We classified each county as urban, suburban, or rural if 50% or more of its Census tracts were categorized as such based on their USDA Rural Urban Commuting Area (RUCA) code. (Source: RUCA code ⁵ ; Paykin et al., 2021 ⁶)
Community health factors	We included county-level measures of income inequality (measured as the ratio of household income at the 80 th percentile to income at the 20 th percentile), uninsured rate, primary care physicians (measured as a ratio of population to primary care physicians), preventable hospital stays (measured as rate of hospital stays for ambulatory-care sensitive conditions per 100K Medicare enrollees), and severe housing problems (measured as percentage of households with at least 1 of 4 housing problems: overcrowding, high housing costs, lack of kitchen facilities, or lack of plumbing facilities). (Source: 2018 County Health Rankings. ⁷)
Internet access	We measured this as the percentage of households without access to the Internet. (Source: ACS 2019 5-year estimates. ⁴)
Group quarter population rates	We measured this as the group quarters population per 100K. (Source: ACS 2019 5-year estimates. ⁴)
Delay in mask mandate policies	The mask mandate variable was calculated by counting how many days a state-level mask mandate was initiated after the county experienced 200 or more

	<p>new cases per 100K based on the 14-day average. We applied this threshold of 200 as CDC defines this as an indicator for high level community transmission: https://covid.cdc.gov/covid-data-tracker/#county-view. (Source: CDC's Public Mask Mandates dataset.⁸)</p>
