Figs. S1 to S3
Tables S1 and S2

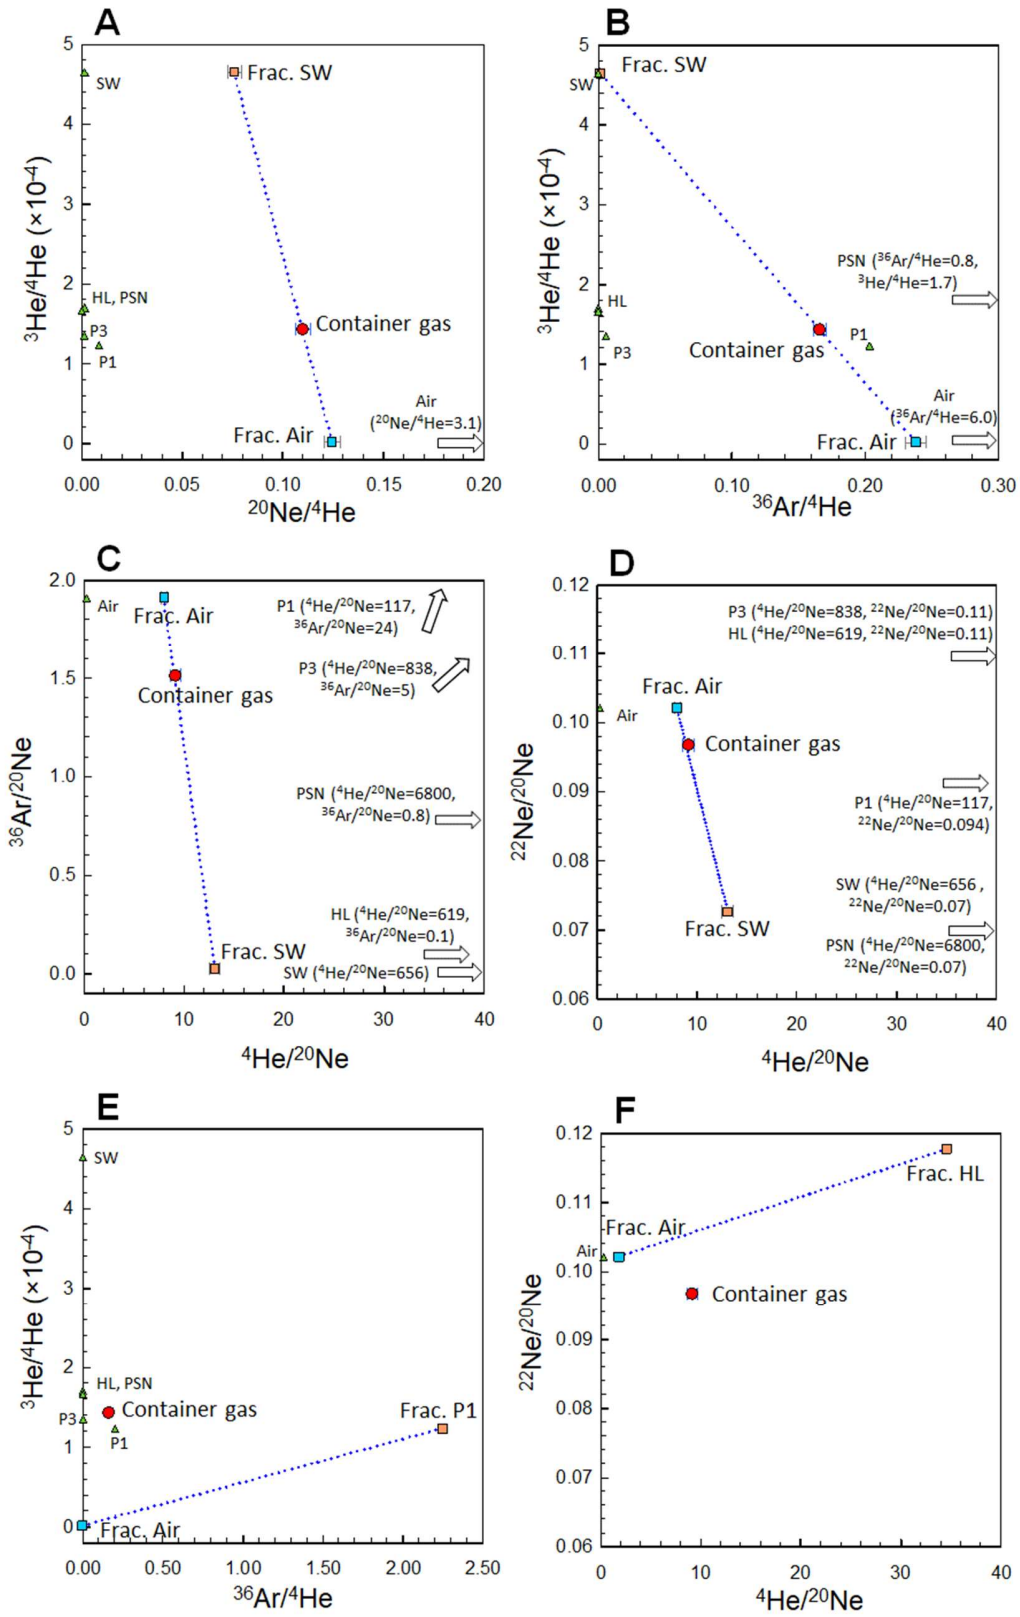

Fig. S1. Reproduction of the container gas composition. The mixing of elementally-

fractionated solar wind (Frac. SW) and terrestrial atmosphere (Frac. Air) explains the observed isotopic and elemental ratios of He and Ne (Figs. S1A–D). Other noble gas components are also plotted for comparison. Two invalid cases are shown in Figs. S1E and S1F for the fractionated P1 and HL components, respectively. PSN denotes Proto Solar Nebula inferred from the Jupiter’s atmosphere (26). Data sources: 15, 16, 23–26.

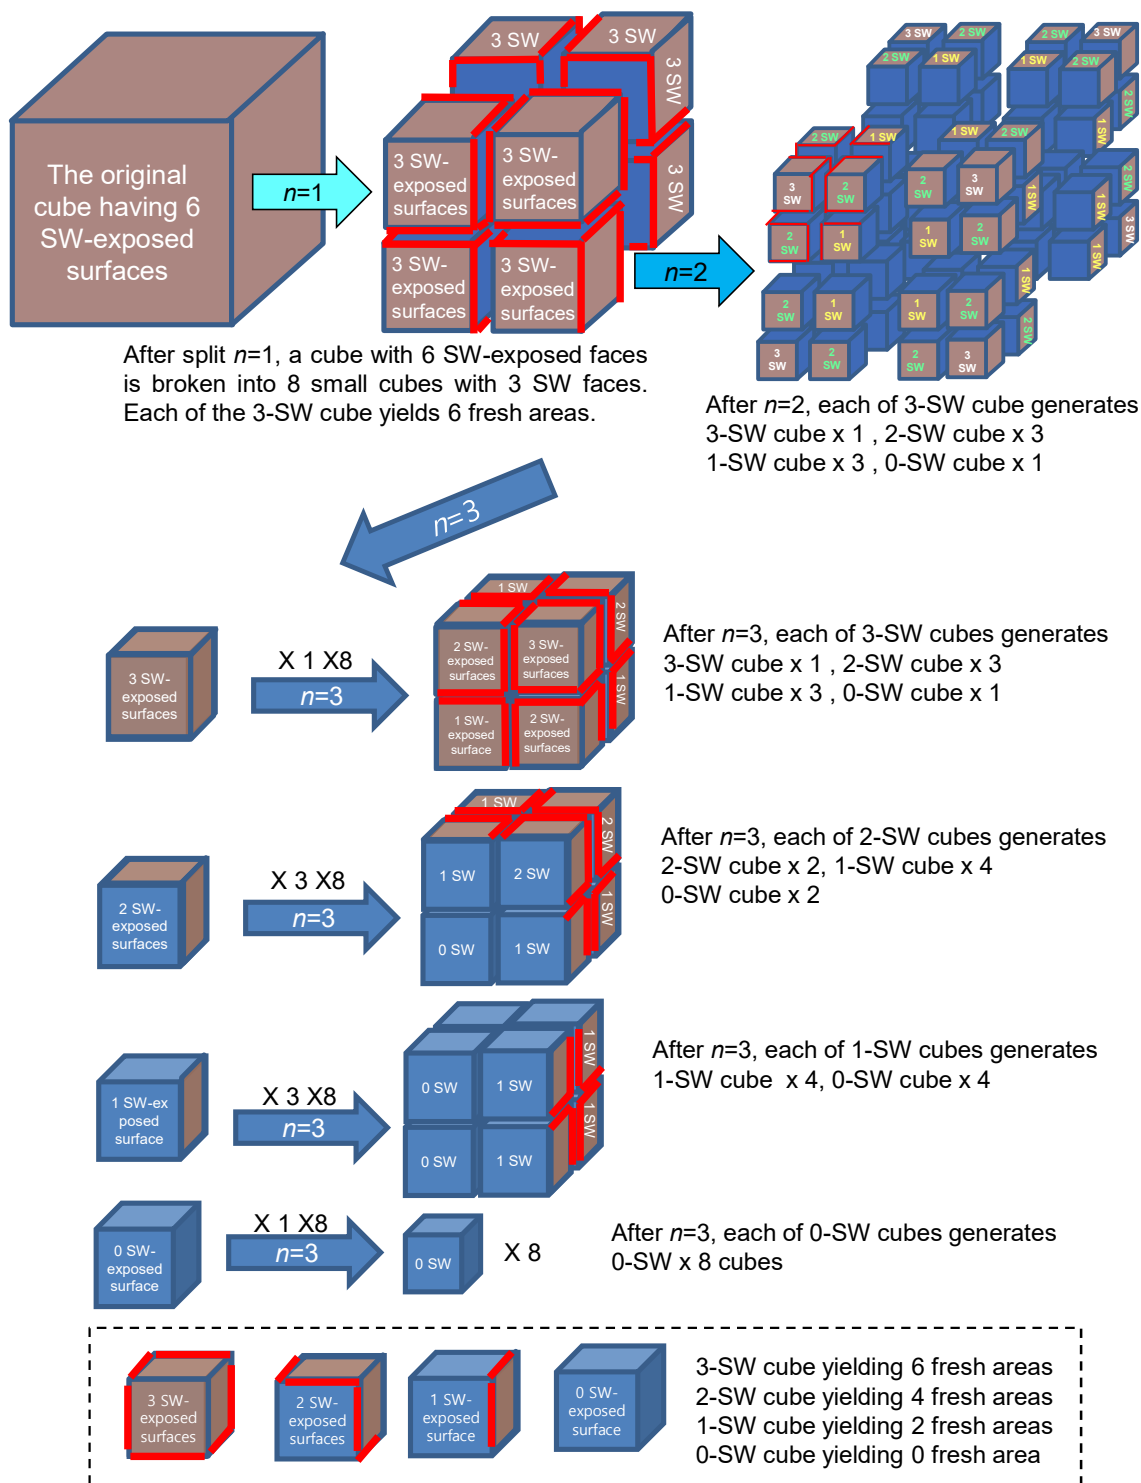

Fig. S2. Conceptual diagram of the calculation of the isotropic fragmentation of the Ryugu grains in the sample container. For example, cubes generated by fragmentation at $n = 1 - 3$ are shown. The red lines indicate the fresh surface areas (cross-sections of the SW-containing layers) generated by fragmentation. SW noble gases are released from these fresh areas.

Fig. S3. Fragmentation model of spherical Ryugu grains. For $n > 1$, variety in the shape of the fragments occur.

Pipette number	Type of pipet	H ₂ [nmol]	O ₂ [nmol]	CH ₄ [nmol]	δ ¹³ C of CH ₄	H ₂ O [nmol]	N ₂ [μmol]	δ ¹⁵ N of N ₂	CO [nmol]	C ₂ H ₆ [nmol]	CO ₂ [nmol]

Average of Haya2 gas*		1.428 ± 0.010	10.3427 ± 0.0050	0.02980 ± 0.00015	0.1099 ± 0.0037	0.1661 ± 0.0048	1.5102 ± 0.0094				

Errors of individual measurements are 1σ.

*The average isotopic ratios of the sample container gas were calculated by weighted averaging of the measurements from the different laboratories. Dispersions of ³He/⁴He ratios (1/σ²) of individual measurements were used as the weighting factor for ³He/⁴He and elemental ratios, except for Ne isotopic ratios (where dispersions of ²⁰Ne/²²Ne and ²¹Ne/²²Ne ratios were used).

Table. S2. Calculation of the fresh SW surface area generated by the isotropic fragmentation.

Fragment. factor n	No. of grains	Side length [cm]	No. of cubes generated				Fresh SW surface [cm ²]	Cumulative surface [cm ²]
			3-SW	2-SW	1-SW	0-SW		
START	1	1	-	-	-	-	-	
1	8	0.5	1	0	0	0	1.20E-04	
2	64	0.25	1	3	3	1	2.40E-04	
3	512	0.125	1	9	27	27	4.80E-04	
4	4096	0.0625	1	21	147	343	9.60E-04	
5	32768	0.03125	1	45	675	3375	1.92E-03	

It is assumed that the original side length is 1 cm and the thickness of the solar wind (SW) concentrated layer is 50 nm. “3-SW” means a cube with 3 SW-exposed faces, and “2-SW” means a cube with 2 SW-exposed faces, and so on. “No. of cubes generated” in the 4th column means the number of cubes generated from each fragment, i.e., the total number of cubes is calculated by multiplying the figure of each cube type by 8 (e.g., for $n = 2$, the total cube number is $(1+3+3+1) \times 8 = 64$). “Fresh SW surface” is area generated at each fragmentation, while “Cumulative surface” is an integrated value of “Fresh SW surface” from which SW gases is expected to be released. Fragmentation should stop when the side length reaches 0.125 cm that is the present (actual) grain size of Ryugu samples (10).
