

S5 Table. Plasticity

Type	Description
mSTDP	<p>\mathbf{W} and \mathbf{Q} initialized separately, uniformly distributed in range $(0, W_{\text{init}})$. For visible unit i, hidden unit j, feedforward learning rate η:</p> $\Delta w_{ij} = \Delta q_{ji} = \eta \sum_{k \in \mathcal{S}_i} \sum_{l \in \mathcal{S}_j} \begin{cases} +e^{- t_l - t_k /\tau_+} & \text{if } t_l > t_k \\ -e^{- t_l - t_k /\tau_-} & \text{if } t_l \leq t_k \end{cases}.$ <p>Weights to-from inhibitory pools $\mathbf{W}_{\text{Vis,Inh}}$ initialized separately from exponential distributions with means $W_{\text{Vis,Inh}}$ etc, and do not undergo plasticity.</p>
Homeostatic adaptation	<p>Synaptic scaling factors initialized to ϕ_{init} or Φ_{init}. $\Delta\phi_j = \Delta\Phi_j = \beta(\rho - A_j)$ ρ = target activation rate, A_j = average activation, initialized equal to 0 and updated after each presentation via</p> $A_j \leftarrow \begin{cases} e^{1/\tau_{\text{fr}}} A_j + (1 - e^{1/\tau_{\text{fr}}}) & \text{if neuron } j \text{ active during the presentation} \\ e^{1/\tau_{\text{fr}}} A_j & \text{otherwise} \end{cases}.$
